Ch10. Dynamic regression models OTexts.org/fpp3/

Outline

- 1 Regression with ARIMA errors
- 2 Stochastic and deterministic trends
- 3 Dynamic harmonic regression
- 4 Lagged predictors

Outline

- 1 Regression with ARIMA errors
- 2 Stochastic and deterministic trends
- 3 Dynamic harmonic regression
- 4 Lagged predictors

Regression models

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \varepsilon_t,$$

- y_t modeled as function of k explanatory variables $x_{1,t}, \ldots, x_{k,t}$.
- In regression, we assume that ε_t was WN.
- Now we want to allow ε_t to be autocorrelated.

Regression models

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \varepsilon_t,$$

- y_t modeled as function of k explanatory variables $x_{1,t}, \ldots, x_{k,t}$.
- In regression, we assume that ε_t was WN.
- Now we want to allow ε_t to be autocorrelated.

Example: ARIMA(1,1,1) errors

$$y_{t} = \beta_{0} + \beta_{1}x_{1,t} + \dots + \beta_{k}x_{k,t} + \eta_{t},$$

$$(1 - \phi_{1}B)(1 - B)\eta_{t} = (1 + \theta_{1}B)\varepsilon_{t},$$

where ε_t is white noise.

Residuals and errors

Example: η_t = ARIMA(1,1,1)

$$y_t = \beta_0 + \beta_1 x_{1,t} + \dots + \beta_k x_{k,t} + \eta_t,$$

 $(1 - \phi_1 B)(1 - B)\eta_t = (1 + \theta_1 B)\varepsilon_t,$

Residuals and errors

Example: η_t = ARIMA(1,1,1)

$$y_t = \beta_0 + \beta_1 x_{1,t} + \dots + \beta_k x_{k,t} + \eta_t,$$

 $(1 - \phi_1 B)(1 - B)\eta_t = (1 + \theta_1 B)\varepsilon_t,$

- Be careful in distinguishing η_t from ε_t .
- Only the errors ε_t are assumed to be white noise.
- In ordinary regression, η_t is assumed to be white noise and so $\eta_t = \varepsilon_t$.

5

Estimation

If we minimize $\sum \eta_t^2$ (by using ordinary regression):

- Estimated coefficients $\hat{\beta}_0, \dots, \hat{\beta}_k$ are no longer optimal as some information ignored;
- 2 Statistical tests associated with the model (e.g., t-tests on the coefficients) are incorrect.
- p-values for coefficients usually too small ("spurious regression').
- 4 AIC of fitted models misleading.

Estimation

If we minimize $\sum \eta_t^2$ (by using ordinary regression):

- Estimated coefficients $\hat{\beta}_0, \dots, \hat{\beta}_k$ are no longer optimal as some information ignored;
- 2 Statistical tests associated with the model (e.g., t-tests on the coefficients) are incorrect.
- p-values for coefficients usually too small ("spurious regression').
- 4 AIC of fitted models misleading.
 - Minimizing $\sum \varepsilon_t^2$ avoids these problems.
 - Maximizing likelihood similar to minimizing $\sum \varepsilon_t^2$.

Stationarity

Regression with ARMA errors

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \eta_t$$
, where η_t is an ARMA process.

- All variables in the model must be stationary.
- If we estimate the model while any of these are non-stationary, the estimated coefficients can be incorrect.
- Difference variables until all stationary.
- If necessary, apply same differencing to all variables.

Stationarity

Model with ARIMA(1,1,1) errors

$$y_t = \beta_0 + \beta_1 x_{1,t} + \cdots + \beta_k x_{k,t} + \eta_t,$$

 $(1 - \phi_1 B)(1 - B)\eta_t = (1 + \theta_1 B)\varepsilon_t,$

Stationarity

Model with ARIMA(1,1,1) errors

$$y_t = \beta_0 + \beta_1 x_{1,t} + \dots + \beta_k x_{k,t} + \eta_t,$$

 $(1 - \phi_1 B)(1 - B)\eta_t = (1 + \theta_1 B)\varepsilon_t,$

Equivalent to model with ARIMA(1,0,1) errors

$$\begin{aligned} \mathbf{y}_t' &= \beta_1 \mathbf{x}_{1,t}' + \dots + \beta_k \mathbf{x}_{k,t}' + \eta_t', \\ (\mathbf{1} - \phi_1 \mathbf{B}) \eta_t' &= (\mathbf{1} + \theta_1 \mathbf{B}) \varepsilon_t, \end{aligned}$$

where
$$y'_t = y_t - y_{t-1}$$
, $x'_{t,i} = x_{t,i} - x_{t-1,i}$ and $\eta'_t = \eta_t - \eta_{t-1}$.

Any regression with an ARIMA error can be rewritten as a regression with an ARMA error by differencing all variables with the same differencing operator as in the ARIMA model.

Any regression with an ARIMA error can be rewritten as a regression with an ARMA error by differencing all variables with the same differencing operator as in the ARIMA model.

Original data

$$y_t = \beta_0 + \beta_1 x_{1,t} + \dots + \beta_k x_{k,t} + \eta_t$$
 where $\phi(B)(1 - B)^d \eta_t = \theta(B)\varepsilon_t$

Any regression with an ARIMA error can be rewritten as a regression with an ARMA error by differencing all variables with the same differencing operator as in the ARIMA model.

Original data

$$\begin{aligned} \mathbf{y}_t &= \beta_0 + \beta_1 \mathbf{x}_{1,t} + \dots + \beta_k \mathbf{x}_{k,t} + \eta_t \\ \text{where} \quad \phi(\mathbf{B}) (1 - \mathbf{B})^d \eta_t &= \theta(\mathbf{B}) \varepsilon_t \end{aligned}$$

After differencing all variables

$$\begin{aligned} \mathbf{y}_t' &= \beta_1 \mathbf{x}_{1,t}' + \dots + \beta_k \mathbf{x}_{k,t}' + \eta_t'. \\ \text{where} \quad \phi(\mathbf{B}) \eta_t &= \theta(\mathbf{B}) \varepsilon_t \\ \text{and} \quad \mathbf{y}_t' &= (\mathbf{1} - \mathbf{B})^d \mathbf{y}_t \end{aligned}$$

Model selection

- Fit regression model with automatically selected ARIMA errors. (R will take care of differencing before estimation.)
- Check that ε_t series looks like white noise.

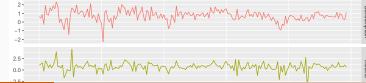

Model selection

- Fit regression model with automatically selected ARIMA errors. (R will take care of differencing before estimation.)
- Check that ε_t series looks like white noise.

Selecting predictors

- AICc can be calculated for final model.
- Repeat procedure for all subsets of predictors to be considered, and select model with lowest AICc value.

```
us change %>%
  gather(key='variable', value='value') %>%
  ggplot(aes(y=value, x=Quarter, group=variabl
  geom_line() + facet_grid(variable ~ ., scale
  xlab("Year") + ylab("") +
  ggtitle("Quarterly changes in US consumption
  guides(colour="none")
 Quarterly changes in US consumption and personal income
```

- No need for transformations or further differencing.
- Increase in income does not necessarily translate into instant increase in consumption (e.g., after the loss of a job, it may take a few months for expenses to be reduced to allow for the new circumstances). We will ignore this for now.

```
fit <- us_change %>% model(ARIMA(Consumption ~ Income))
report(fit)
```

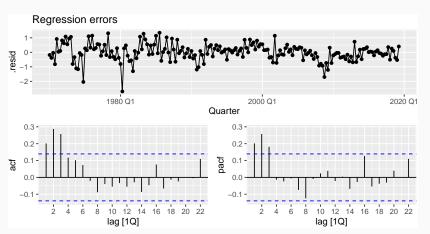

```

Forecasting

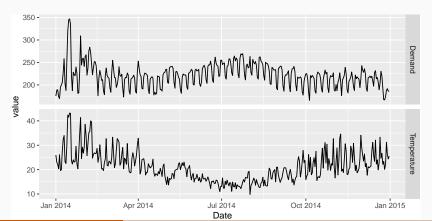

- To forecast a regression model with ARIMA errors, we need to forecast the regression part of the model and the ARIMA part of the model and combine the results.
- Some predictors are known into the future (e.g., time, dummies).
- Separate forecasting models may be needed for other predictors.
- Forecast intervals ignore the uncertainty in forecasting the predictors.

Model daily electricity demand as a function of temperature using quadratic regression with ARMA errors.

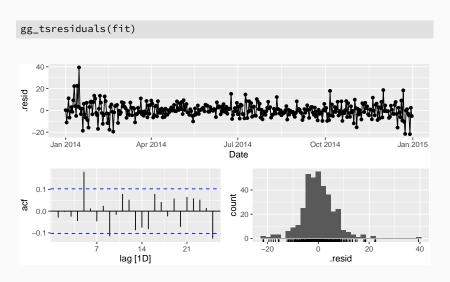

```
vic_elec_daily %>%
  ggplot(aes(x=Temperature, y=Demand, colour=Day_Type)) +
  geom_point() +
  labs(x = "Maximum temperature", y = "Electricity demand (GW)")
```

```
vic_elec_daily %>%
  gather("var", "value", Demand, Temperature) %>%
  ggplot(aes(x = Date, y = value)) + geom_line() +
  facet_grid(vars(var), scales = "free_y")
```

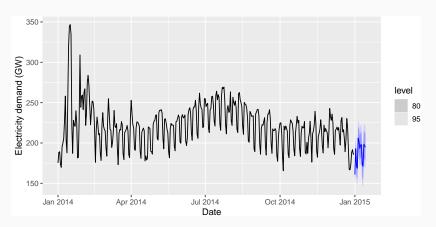

```
fit <- vic elec daily %>%
 model(ARIMA(Demand ~ Temperature + I(Temperature^2) +
               (Day Type=="Weekday")))
report(fit)

Outline

- 1 Regression with ARIMA errors
- 2 Stochastic and deterministic trends
- 3 Dynamic harmonic regression
- 4 Lagged predictors

Stochastic & deterministic trends

Deterministic trend

$$y_t = \beta_0 + \beta_1 t + \eta_t$$

where η_t is ARMA process.

Stochastic & deterministic trends

Deterministic trend

$$y_t = \beta_0 + \beta_1 t + \eta_t$$

where η_t is ARMA process.

Stochastic trend

$$y_t = \beta_0 + \beta_1 t + \eta_t$$

where η_t is ARIMA process with $d \geq 1$.

Stochastic & deterministic trends

Deterministic trend

$$y_t = \beta_0 + \beta_1 t + \eta_t$$

where η_t is ARMA process.

Stochastic trend

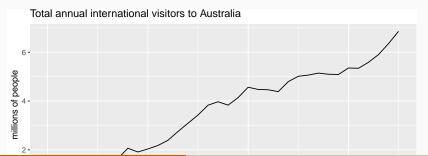

$$y_t = \beta_0 + \beta_1 t + \eta_t$$

where η_t is ARIMA process with $d \geq 1$.

Difference both sides until η_t is stationary:

$$\mathbf{y}_t' = \beta_1 + \eta_t'$$

where η'_t is ARMA process.

Deterministic trend

```
fit_deterministic <- aus_visitors %>%
 model(Deterministic = ARIMA(value ~ trend() + pdg(d = 0)))
report(fit_deterministic)

                  y_t - y_{t-1} = 0.173 + \varepsilon_t + 0.301\varepsilon_{t-1}
                        y_t = y_0 + 0.173t + \eta_t
```

 $\eta_t = \eta_{t-1} + 0.301\varepsilon_{t-1} + \varepsilon_t$

```
fc_deterministic <- forecast(fit_deterministic</pre>
fc_stochastic <- forecast(fit_stochastic, h =</pre>
rbind(fc_deterministic, fc_stochastic) %>%
  autoplot(aus_visitors) +
  facet_grid(vars(.model)) +
  labs(x = "Year", y = "Visitors to Australia
       title = "Forecasts from trend models")
  guides(colour = FALSE)
```

Forecasting with trend

- Point forecasts are almost identical, but prediction intervals differ.
- Stochastic trends have much wider prediction intervals because the errors are non-stationary.
- Be careful of forecasting with deterministic trends too far ahead.

Outline

- 1 Regression with ARIMA errors
- 2 Stochastic and deterministic trends
- 3 Dynamic harmonic regression
- 4 Lagged predictors

Dynamic harmonic regression

Combine Fourier terms with ARIMA errors

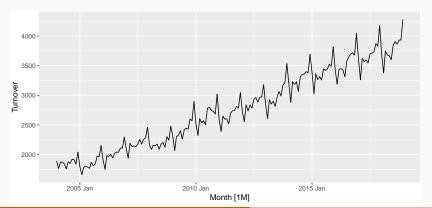

Advantages

- it allows any length seasonality;
- for data with more than one seasonal period, you can include Fourier terms of different frequencies;
- the seasonal pattern is smooth for small values of K (but more wiggly seasonality can be handled by increasing K);
- the short-term dynamics are easily handled with a simple ARMA error.

Disadvantages

seasonality is assumed to be fixed

```
aus_cafe <- aus_retail %>% filter(
    Industry == "Cafes, restaurants and takeaway food services",
    year(Month) %in% 2004:2018
) %>% summarise(Turnover = sum(Turnover))
aus_cafe %>% autoplot(Turnover)
```

```
fit <- aus_cafe %>% model(
    `K = 1` = ARIMA(log(Turnover) ~ fourier(K = 1) + PDQ(0,0,0)),
    `K = 2` = ARIMA(log(Turnover) ~ fourier(K = 2) + PDQ(0,0,0)),
    `K = 3` = ARIMA(log(Turnover) ~ fourier(K = 3) + PDQ(0,0,0)),
    `K = 4` = ARIMA(log(Turnover) ~ fourier(K = 4) + PDQ(0,0,0)),
    `K = 5` = ARIMA(log(Turnover) ~ fourier(K = 5) + PDQ(0,0,0)),
    `K = 6` = ARIMA(log(Turnover) ~ fourier(K = 6) + PDQ(0,0,0)))

Outline

- 1 Regression with ARIMA errors
- 2 Stochastic and deterministic trends
- 3 Dynamic harmonic regression
- 4 Lagged predictors

Sometimes a change in x_t does not affect y_t instantaneously

Sometimes a change in x_t does not affect y_t instantaneously

- y_t = sales, x_t = advertising.
- y_t = stream flow, x_t = rainfall.
- y_t = size of herd, x_t = breeding stock.

Sometimes a change in x_t does not affect y_t instantaneously

- y_t = sales, x_t = advertising.
- y_t = stream flow, x_t = rainfall.
- y_t = size of herd, x_t = breeding stock.
- These are dynamic systems with input (x_t) and output (y_t) .
- \blacksquare x_t is often a leading indicator.
- There can be multiple predictors.

The model include present and past values of predictor: $x_t, x_{t-1}, x_{t-2}, \ldots$

$$y_t = a + \gamma_0 x_t + \gamma_1 x_{t-1} + \cdots + \gamma_k x_{t-k} + \eta_t$$

where η_t is an ARIMA process.

The model include present and past values of predictor: $x_t, x_{t-1}, x_{t-2}, \ldots$

$$y_t = a + \gamma_0 x_t + \gamma_1 x_{t-1} + \cdots + \gamma_k x_{t-k} + \eta_t$$

where η_t is an ARIMA process.

Rewrite model as

$$y_t = a + (\gamma_0 + \gamma_1 B + \gamma_2 B^2 + \dots + \gamma_k B^k) x_t + \eta_t$$

= $a + \gamma(B) x_t + \eta_t$.

The model include present and past values of predictor: $x_t, x_{t-1}, x_{t-2}, \ldots$

$$y_t = a + \gamma_0 x_t + \gamma_1 x_{t-1} + \dots + \gamma_k x_{t-k} + \eta_t$$

where η_t is an ARIMA process.

Rewrite model as

$$y_t = a + (\gamma_0 + \gamma_1 B + \gamma_2 B^2 + \dots + \gamma_k B^k) x_t + \eta_t$$

= $a + \gamma(B) x_t + \eta_t$.

- $\gamma(B)$ is called a *transfer function* since it describes how change in x_t is transferred to y_t .
- *x* can influence *y*, but *y* is not allowed to influence *x*.
